Dear Editor,

Please consider the enclosed manuscript, “*Residual Radial Structure in SPARC Dark Matter Halos Reproduces on Independently Derived Rotation Curves*,” for publication in *The Astrophysical Journal Letters*.

Single smooth equilibrium halo profiles leave statistically significant, radially organized residuals in $\sim 35\%$ of SPARC rotation curves. Because such a detection could reflect fitting-basis flexibility or a systematic of one velocity-field extraction rather than a property of the galaxies, this Letter reports the most direct test of galaxy-intrinsic origin: whether the model selection reproduces when rotation curves are re-derived from the original radio data cubes by independent software, holding the baryonic model fixed. It does, in four of five adjudicable systems — decisively for NGC 2403 ($\Delta\text{BIC} = 121$, on a curve derived from different observations) and NGC 3198 ($\Delta\text{BIC} = 55$) — with the crossover radius preserved; the one non-reproduction and one power-limited case are reported explicitly. Because SPARC underpins a large body of current work on dark matter halo structure, we believe this concise, single-result verification is of immediate and broad interest, and is naturally suited to the Letters format.

A companion paper presenting the full method-independence and robustness program is in preparation and is cited in the manuscript as Bibb 2026b; the present Letter is fully self-contained. The manuscript is not under consideration elsewhere, and no presubmission inquiry was made. All code, pipeline configurations, and derived data products are openly archived (Zenodo, DOI 10.5281/zenodo.21196421) and developed at github.com/RonBibb/sparc-sphere. The warp-aware rotation curves for NGC 2841 and NGC 3521 were provided by J. Sellwood and K. Spekkens and are credited as private communication in the text.

Thank you for your consideration.

Sincerely,

Ron Bibb
